

## CS 361, Lecture 13

Jared Saia  
University of New Mexico

- Appendix C.1 in the book is an excellent reference for background math on counting
- Appendix C.2 is good background for probability

2

## Outline

- Lower Bound for Sorting by Comparison
- Bucket Sort
- Dictionary ADT

1

## How Fast Can We Sort?

- Q: What is a lowerbound on the runtime of any sorting algorithm?
- We know that  $\Omega(n)$  is a trivial lowerbound
- But all the algorithms we've seen so far are  $O(n \log n)$  (or  $O(n^2)$ ), so is  $\Omega(n \log n)$  a lowerbound?

3

## Comparison Sorts

- Definition: An sorting algorithm is a *comparison sort* if the sorted order they determine is based only on comparisons between input elements.
- Heapsort, mergesort, quicksort, bubblesort, and insertion sort are all comparison sorts
- We will show that any comparison sort must take  $\Omega(n \log n)$

4

## Comparisons

- Assume we have an input sequence  $A = (a_1, a_2, \dots, a_n)$
- In a comparison sort, we only perform tests of the form  $a_i < a_j$ ,  $a_i \leq a_j$ ,  $a_i = a_j$ ,  $a_i \geq a_j$ , or  $a_i > a_j$  to determine the relative order of all elements in  $A$
- We'll assume that all elements are distinct, and so note that the only comparison we need to make is  $a_i \leq a_j$ .
- This comparison gives us a yes or no answer

5

## Decision Tree Model

- A decision tree is a full binary tree that gives the possible sequences of comparisons made for a particular input array,  $A$
- Each internal node is labelled with the indices of the two elements to be compared
- Each leaf node gives a permutation of  $A$

6

## Decision Tree Model

- The execution of the sorting algorithm corresponds to a path from the root node to a leaf node in the tree.
- We take the left child of the node if the comparison is  $\leq$  and we take the right child if the comparison is  $>$
- The internal nodes along this path give the comparisons made by the alg, and the leaf node gives the output of the sorting algorithm.

7

## Leaf Nodes

- Any correct sorting algorithm must be able to produce each possible permutation of the input
- Thus there must be at least  $n!$  leaf nodes
- The length of the longest path from the root node to a leaf in this tree gives the worst case run time of the algorithm (i.e. the height of the tree gives the worst case runtime)

8

## Example

- Consider the problem of sorting an array of size two:  $A = (a_1, a_2)$
- Following is a decision tree for this problem.

9

## In-Class Exercise

- Give a decision tree for sorting an array of size three:  $A = (a_1, a_2, a_3)$
- What is the height? What is the number of leaf nodes?

10

## Height of Decision Tree

- Q: What is the height of a binary tree with at least  $n!$  leaf nodes?
- A: If  $h$  is the height, we know that  $2^h \geq n!$
- Taking log of both sides, we get  $h \geq \log(n!)$

11

## Height of Decision Tree

- Q: What is  $\log(n!)$ ?
- A: It is

$$\begin{aligned}\log(n * (n-1) * \dots * 1) &= \log n + \log(n-1) + \dots + \log 1 \\ &\geq (n/2) \log(n/2) \\ &\geq (n/2)(\log n - \log 2) \\ &= \Omega(n \log n)\end{aligned}$$

- Thus any decision tree for sorting  $n$  elements will have a height of  $\Omega(n \log n)$

12

## Take Away

- We've just proven that any comparison-based sorting algorithm takes  $\Omega(n \log n)$  time
- This does *not* mean that *all* sorting algorithms take  $\Omega(n \log n)$  time
- In fact, there are non comparison-based sorting algorithms which, under certain circumstances, are asymptotically faster.

13

## Bucket Sort

- Bucket sort assumes that the input is drawn from a uniform distribution over the range  $[0, 1)$
- Basic idea is to divide the interval  $[0, 1)$  into  $n$  equal size regions, or buckets
- We expect that a small number of elements in  $A$  will fall into each bucket
- To get the output, we can sort the numbers in each bucket and just output the sorted buckets in order

14

## Bucket Sort

```
//PRE: A is the array to be sorted, all elements in A[i] are between
//POST: returns a list which is the elements of A in sorted order
BucketSort(A){
    B = new List[]
    n = length(A)
    for (i=1; i<=n; i++){
        insert A[i] at end of list B[floor(n*A[i])];
    }
    for (i=0; i<=n-1; i++){
        sort list B[i] with insertion sort;
    }
    return the concatenated list B[0], B[1], ..., B[n-1];
}
```

15

## Bucket Sort

- Claim: If the input numbers are distributed uniformly over the range  $[0, 1)$ , then Bucket sort takes expected time  $O(n)$
- Let  $T(n)$  be the run time of bucket sort on a list of size  $n$
- Let  $n_i$  be the random variable giving the number of elements in bucket  $B[i]$
- Then  $T(n) = \Theta(n) + \sum_{i=0}^{n-1} O(n_i^2)$

16

## Analysis

- We know  $T(n) = \Theta(n) + \sum_{i=0}^{n-1} O(n_i^2)$
- Taking expectation of both sides, we have

$$\begin{aligned} E(T(n)) &= E\left(\Theta(n) + \sum_{i=0}^{n-1} O(n_i^2)\right) \\ &= \Theta(n) + \sum_{i=0}^{n-1} E(O(n_i^2)) \\ &= \Theta(n) + \sum_{i=0}^{n-1} (O(E(n_i^2))) \end{aligned}$$

- The second step follows by linearity of expectation
- The last step holds since for any constant  $a$  and random variable  $X$ ,  $E(aX) = aE(X)$  (see Equation C.21 in the text)

17

## Analysis

- We claim that  $E(n_i^2) = 2 - 1/n$
- To prove this, we define indicator random variables:  $X_{ij} = 1$  if  $A[j]$  falls in bucket  $i$  and 0 otherwise (defined for all  $i$ ,  $0 \leq i \leq n-1$  and  $j$ ,  $1 \leq j \leq n$ )
- Thus,  $n_i = \sum_{j=1}^n X_{ij}$
- We can now compute  $E(n_i^2)$  by expanding the square and regrouping terms

18

## Analysis

$$\begin{aligned} E(n_i^2) &= E\left(\left(\sum_{j=1}^n X_{ij}\right)^2\right) \\ &= E\left(\sum_{j=1}^n \sum_{k=1}^n X_{ij} X_{ik}\right) \\ &= E\left(\sum_{j=1}^n X_{ij}^2 + \sum_{1 \leq j < k \leq n} \sum_{1 \leq k \leq n, k \neq j} X_{ij} X_{ik}\right) \\ &= \sum_{j=1}^n E(X_{ij}^2) + \sum_{1 \leq j < k \leq n} \sum_{1 \leq k \leq n, k \neq j} E(X_{ij} X_{ik}) \end{aligned}$$

19

## Analysis

- We can evaluate the two summations separately.  $X_{ij}$  is 1 with probability  $1/n$  and 0 otherwise
- Thus  $E(X_{ij}^2) = 1 * (1/n) + 0 * (1 - 1/n) = 1/n$
- Where  $k \neq j$ , the random variables  $X_{ij}$  and  $X_{ik}$  are independent
- For any two *independent* random variables  $X$  and  $Y$ ,  $E(XY) = E(X)E(Y)$  (see C.3 in the book for a proof of this)
- Thus we have that

$$\begin{aligned} E(X_{ij}X_{ik}) &= E(X_{ij})E(X_{ik}) \\ &= (1/n)(1/n) \\ &= (1/n^2) \end{aligned}$$

20

## Analysis

- Recall that  $E(T(n)) = \Theta(n) + \sum_{i=0}^{n-1} (O(E(n_i^2)))$
- We can now plug in the equation  $E(n_i^2) = 2 - (1/n)$  to get

$$\begin{aligned} E(T(n)) &= \Theta(n) + \sum_{i=0}^{n-1} 2 - (1/n) \\ &= \Theta(n) + \Theta(n) \\ &= \Theta(n) \end{aligned}$$

- Thus the entire bucket sort algorithm runs in expected linear time

22

## Analysis

- Substituting these two expected values back into our main equation, we get:

$$\begin{aligned} E(n_i^2) &= \sum_{j=1}^n E(X_{ij}^2) + \sum_{1 \leq j \leq n} \sum_{1 \leq k \leq n, k \neq j} E(X_{ij}X_{ik}) \\ &= \sum_{j=1}^n (1/n) + \sum_{1 \leq j \leq n} \sum_{1 \leq k \leq n, k \neq j} (1/n^2) \\ &= n(1/n) + (n)(n-1)(1/n^2) \\ &= 1 + (n-1)/n \\ &= 2 - (1/n) \end{aligned}$$

21

## Dictionary ADT

A dictionary ADT implements the following operations

- *Insert(x)*: puts the item  $x$  into the dictionary
- *Delete(x)*: deletes the item  $x$  from the dictionary
- *IsIn(x)*: returns true iff the item  $x$  is in the dictionary

23

## Dictionary ADT

- Frequently, we think of the items being stored in the dictionary as *keys*
- The keys typically have *records* associated with them which are carried around with the key but not used by the ADT implementation
- Thus we can implement functions like:
  - *Insert(k,r)*: puts the item (k,r) into the dictionary if the key k is not already there, otherwise returns an error
  - *Delete(k)*: deletes the item with key k from the dictionary
  - *Lookup(k)*: returns the item (k,r) if k is in the dictionary, otherwise returns null

24

## In-Class Exercise

Implement a dictionary with a linked list

- Q1: Write the operation *Lookup(k)* which returns a pointer to the item with key k if it is in the dictionary or null otherwise
- Q2: Write the operation *Insert(k,r)*
- Q3: Write the operation *Delete(k)*
- Q4: For a dictionary with  $n$  elements, what is the runtime of all of these operations for the linked list data structure?
- Q5: Describe how you would use this dictionary ADT to count the number of occurrences of each word in an online book.

26

## Implementing Dictionaries

- The simplest way to implement a dictionary ADT is with a linked list
- Let  $l$  be a linked list data structure, assume we have the following operations defined for  $l$ 
  - *head(l)*: returns a pointer to the head of the list
  - *next(p)*: given a pointer  $p$  into the list, returns a pointer to the next element in the list if such exists, null otherwise
  - *previous(p)*: given a pointer  $p$  into the list, returns a pointer to the previous element in the list if such exists, null otherwise
  - *key(p)*: given a pointer into the list, returns the key value of that item
  - *record(p)*: given a pointer into the list, returns the record value of that item

25

## Dictionaries

- This linked list implementation of dictionaries is very slow
- Q: Can we do better?
- A: Yes, with hash tables, AVL trees, etc

27

## Hash Tables

Hash Tables implement the Dictionary ADT, namely:

- Insert( $x$ ) -  $O(1)$  expected time,  $\Theta(n)$  worst case
- Lookup( $x$ ) -  $O(1)$  expected time,  $\Theta(n)$  worst case
- Delete( $x$ ) -  $O(1)$  expected time,  $\Theta(n)$  worst case

28

## Direct Addressing

- Suppose universe of keys is  $U = \{0, 1, \dots, m - 1\}$ , where  $m$  is not too large
- Assume no two elements have the same key
- We use an array  $T[0..m - 1]$  to store the keys
- Slot  $k$  contains the elem with key  $k$

29

## Direct Address Functions

```
DA-Search(T,k){ return T[k];}  
DA-Insert(T,x){ T[key(x)] = x;}  
DA-Delete(T,x){ T[key(x)] = NIL;}
```

Each of these operations takes  $O(1)$  time

30

## Direct Addressing Problem

- If universe  $U$  is large, storing the array  $T$  may be impractical
- Also much space can be wasted in  $T$  if number of objects stored is small
- Q: Can we do better?
- A: Yes we can trade time for space

31
