CS 461, Lecture 11

Jared Saia University of New Mexico

Today's Outline _____

- Midterm Post Mortem
- Amortized Analysis

Rough ranges for grades are as follows:

- 90-100 A
- 70-90 B
- 60-70 C
- 0- 60 F

Amortized Analysis ———

"I will gladly pay you Tuesday for a hamburger today" - Wellington Wimpy

- In amortized analysis, time required to perform a sequence of data structure operations is averaged over all the operations performed
- Typically used to show that the average cost of an operation is small for a sequence of operations, even though a single operation can cost a lot

Aggregate Analysis _____

Amortized analysis is not average case analysis.

- Average Case Analysis: the expected cost of each operation
- Amortized analysis: the average cost of each operation in the worst case
- Probability is not involved in amortized analysis

• We get an upperbound T(n) on the total cost of a sequence of n operations. The average cost per operation is then T(n)/n, which is also the amortized cost per operation

4

6

Types of Amortized Analysis _____

Stack with Multipop _____

- Aggregate Analysis
- Accounting or Taxation Method
- Potential method
- We'll see each method used for 1) a stack with the additional operation MULTIPOP and 2) a binary counter

- Recall that a standard stack has the operations PUSH and POP
- Each of these operations runs in O(1) time, so let's say the cost of each is 1
- Now for a stack S and number k, let's add the operation MULTIPOP which removes the top k objects on the stack
- ullet Multipop just calls Pop either k times or until the stack is empty

_ Multipop _	
--------------	--

The Problem ____

- Q: What is the running time of Multipop(S,k) on a stack of s objects?
- A: The cost is min(s,k) pop operations
- If there are n stack operations, in the worst case, a single Multipop can take O(n) time

- This analysis is technically correct, but overly pessimistic
- While some of the multipop operations can take O(n) time, not all of them can
- ullet We need some way to average over the entire sequence of n operations

8

Multipop Analysis _____

Aggregate Analysis _____

- ullet Let's analyze a sequence of n push, pop, and multipop operations on an initially empty stack
- The worst case cost of a multipop operation is O(n) since the stack size is at most n, so the worst case time for any operation is O(n)
- Hence a sequence of n operations costs $O(n^2)$

- In fact, the total cost of n operations on an initially empty stack is O(n)
- Why? Because each object can be popped at most once for each time that it is pushed
- Hence the number of times POP (including calls within Multipop) can be called on a nonempty stack is at most the number of Push operations which is O(n)

10

Binary Counter ____

- Hence for any value of n, any sequence of n Push, Pop, and Multipop operations on an initially empty stack takes O(n) time
- The average cost of an operation is thus O(n)/n = O(1)
- Thus all stack operations have an amortized cost of O(1)

- Initially x = 0 so A[i] = 0 for all $i = 0, 1, \dots, k-1$
- To add 1 to the counter, we use a simple procedure which scans the bits from right to left, zeroing out 1's until it finally find a zero bit which it flips to a 1

12

14

Another Example ____

Increment ____

Another example where we can use aggregate analysis:

- ullet Consider the problem of creating a k bit binary counter that counts upward from 0
- ullet We use an array A[0..k-1] of bits as the counter
- A binary number x that is stored in A has its lowest-order bit in A[0] and highest order bit in A[k-1] $(x = \sum_{i=0}^{k-1} A[i] * 2^i)$

```
Increment(A) {
   i = 0;
   while(i < k & A[i] = 1) {
        A[i] = 0;
        i++;
   }
   if (i < k)
        A[i] = 1;
}</pre>
```

	Ana	lysis	
•	,	. ,	

Aggregate Analysis _____

- ullet It's not hard to see that in the worst case, the increment procedure takes time $\Theta(k)$
- ullet Thus a sequence of n increments takes time O(nk) in the worst case
- Note that again this bound is correct but overly pessimistic
 not all bits flip each time increment is called!

• In general, for $i=0,\dots \lfloor \log n \rfloor$, bit A[i] flips $\lfloor n/2^i \rfloor$ times in a sequence of n calls to Increment on an initially zero counter

- For $i > |\log n|$, bit A[i] never flips
- \bullet Total number of flips in the sequence of n calls is thus

$$\sum_{i=0}^{\lfloor \log n \rfloor} \left\lfloor \frac{n}{2^i} \right\rfloor < n \sum_{i=0}^{\infty} \frac{1}{2^i}$$
 (1)

$$= 2n \tag{2}$$

16

18

Aggregate Analysis _____

. Aggregate Analysis _____

- In fact, we can show that a sequence of n calls to Increment has a worst case time of O(n)
- A[0] flips every time Increment is called, A[1] flips over every other time, A[2] flips over every fourth time, . . .
- Thus if there are n calls to increment, A[0] flips n times, A[1] flips $\lfloor n/2 \rfloor$ times, A[2] flips $\lfloor n/4 \rfloor$ times

- Thus the worst-case time for a sequence of n Increment operations on an initially empty counter is O(n)
- The average cost of each operation in the worst case then is O(n)/n = O(1)

Accounting or Taxation Method _____

___ Taxation Method _____

- The second method is called the accounting method in the book, but a better name might be the *taxation* method
- Suppose it costs us a dollar to do a Push or Pop
- We can then measure the run time of our algorithm in dollars (Time is money!)

• Like any good government (ha ha) we need to make sure that: 1) our taxes are low and 2) we can use our taxes to pay for all our costs

- ullet We already know that our taxes for n operations are no more than 2n dollars
- We now want to show that we can use the 2 dollars we collect for each push to pay for all the push, pop and multipop operations

20

22

Taxation Method for Multipop _____

Taxation Method _____

- Instead of paying for each Push and Pop operation when they occur, let's tax the pushes to pay for the pops
- I.e. we tax the push operation 2 dollars, and the pop and multipop operations 0 dollars
- Then each time we do a push, we spend one dollar of the tax to pay for the push and then *save* the other dollar of the tax to pay for the inevitable pop or multipop of that item
- ullet Note that if we do n operations, the total amount of taxes we collect is then 2n

- This is easy to show. When we do a push, we use 1 dollar of the tax to pay for the push and then store the extra dollar with the item that was just pushed on the stack
- Then all items on the stack will have one dollar stored with them
- Whenever we do a Pop, we can use the dollar stored with the item popped to pay for the cost of that Pop
- Moreover, whenever we do a Multipop, for each item that we pop off in the Multipop, we can use the dollar stored with that item to pay for the cost of popping that item

Taxation Method _____

Taxation Scheme _____

- We've shown that we can use the 2 tax on each item pushed to pay for the cost of all pops, pushes and multipops.
- Moreover we know that this taxation scheme collects at most 2n dollars in taxes over n stack operations
- ullet Hence we've shown that the amortized cost per operation is O(1)

Taxation Method for Binary Counter

- Let's now use the taxation method to show that the amortized cost of the Increment algorithm is O(1)
- Let's say that it costs us 1 dollar to flip a bit
- What is a good taxation scheme to ensure that we can pay for the costs of all flips but that we keep taxes low?

- Let's tax the algorithm 2 dollars to set a bit to 1
- Now we need to show that: 1) this scheme has low total taxes and 2) we will collect enough taxes to pay for all of the bit flips
- Showing overall taxes are low is easy: Each time Increment is called, it sets at most one bit to a 1
- So we collect exactly 2 dollars in taxes each time increment is called
- \bullet Thus over n calls to Increment, we collect 2n dollars in taxes

__ Taxation Scheme ____

- We now need to show that our taxation scheme has enough money to pay for the costs of all operations
- This is easy: Each time we set a bit to a 1, we collect 2 dollars in tax. We use one dollar to pay for the cost of setting the bit to a 1, then we *store* the extra dollar on that bit
- When the bit gets flipped back from a 1 to a 0, we use the dollar already on that bit to pay for the cost of the flip!

26

Binary (Counter	
----------	---------	--

In Class Exercise _____

- We've shown that we can use the 2 tax each time a bit is set to a 1 to pay for all operations which flip a bit
- ullet Moreover we know that this taxation scheme collects 2n dollars in taxes over n calls to Increment
- ullet Hence we've shown that the amortized cost per call to Increment is O(1)

- ullet A sequence of Pushes and Pops is performed on a stack whose size never exceeds k
- After every k operations, a copy of the entire stack is made for backup purposes
- Show that the cost of n stack operations, including copying the stack, is O(n)

28

30

In Class Exercise ____

____ In Class Exercise ____

- ullet A sequence of Pushes and Pops is performed on a stack whose size never exceeds k
- After every k operations, a copy of the entire stack is made for backup purposes
- Show that the cost of n stack operations, including copying the stack, is O(n)

- Q1: What is your taxation scheme?
- Q2: What is the maximum amount of taxes this scheme collects over *n* operations?
- Q3: Show that your taxation scheme can pay for the costs of all operations
